#### Perceived Income Risks

 $\begin{tabular}{ll} Tao\ Wang \\ Johns\ Hopkins\ University \end{tabular}$ 

February 3, 2022 Macro/Finance Brownbag Seminar

#### Outline

- Motivation
- 2 Theoretical framework
- 3 Empirical evidence
  - Cross-sectional patterns
  - Permanent versus transitory risks
  - Perceived risks and macroeconomic history
  - Extrapolation of recent experience
  - Countercyclical perceived risks
  - Perceived unemployment risks
  - Perceived risks and decisions
  - Summary of empirical findings
- Model
- 6 Conclusion

#### Motivation

- Risks matter for individual decisions
  - precautionary saving
  - stock market participation
  - portfolio choice
- Risks matter for macroeconomic outcomes
  - since idiosyncratic risks are not perfectly insured
    - $\bullet$   $\rightarrow$  income/wealth inequality
    - $\bullet$   $\rightarrow$  heterogeneous MPCs
    - $\bullet$   $\rightarrow$  distributional channel of macroeconomic policies
    - $\bullet$   $\rightarrow$  business cycle fluctuations
- Income risks are central inputs of any incomplete-market model
- My question: perceptions  $\approx$  estimates  $\approx$  "the truth"?

#### Some macro facts

- $\bullet$  Wealth inequality and heterogeneity in MPCs
  - a standard incomplete market model generates insufficient inequality seen in the data
  - unless additional features such as preference heterogeneity or costly adjustment are introduced
- Liquid assets holdings
  - too few in data compared to a standard one-asset incomplete market model
- "Excessive sensitivity" to unanticipated transitory shocks
  - high MPCs seen in the data than PIH model prediction

# Preview of the findings

- Empirics: subjective risk profiles from a density survey
  - Heterogeneity: sizable difference across/within groups
  - Superior information: on average lower than standard parameterizations used by economists
  - State-dependence: negative correlation with recent/past labor market conditions
  - Extrapolation: correlated with negative labor outcomes
  - History-dependence: positive correlation with experienced volatility/unemployment
  - Decisions: spending plans react to risk perceptions

# Preview of the findings

- Empirics: subjective risk profiles from a density survey
  - Heterogeneity: sizable difference across/within groups
  - Superior information: on average lower than standard parameterizations used by economists
  - State-dependence: negative correlation with recent/past labor market conditions
  - Extrapolation: correlated with negative labor outcomes
  - History-dependence: positive correlation with experienced volatility/unemployment
  - Decisions: spending plans react to risk perceptions

#### Model:

- a survey-informed subjective OLG / incomplete-market GE model
  - Lower PR  $\rightarrow$  lower savings
  - State-dependence/extrapolation  $\rightarrow$  higher savings
  - Heterogeneity in  $PR \rightarrow$  wealth inequality

#### Literature

- income risks and partial insurance :Gottschalk et al. (1994), Carroll and Samwick (1997), Meghir and Pistaferri (2004), Storesletten et al. (2004), Blundell et al. (2008), Moffitt and Gottschalk (2002), Guvenen et al. (2014), Arellano et al. (2017), Bloom et al. (2018)
- subjective/probabilistic survey of beliefs: Manski (2004), Delavande et al. (2011), Manski (2018), Bertrand and Mullainathan (2001), Armantier et al. (2017)
- incomplete market macro: Bewley (1976), Aiyagari (1994), Huggett (1996), Krusell and Smith (1998), Heathcote et al. (2009), Carroll et al. (2017), Krueger et al. (2016), Bayer et al. (2019)
- consumption/saving under incomplete information/imperfect perception: Pischke (1995), Wang (2004), Rozsypal and Schlafmann (2017), Carroll et al. (2018), Lian (2019)

#### Log income process

$$y_{i,c,t} = z_{i,c,t} + e_{i,c,t}$$
idiosyncratic log earning predictable component stochastic component

- $\bullet$  individual i at time t
- group c: share income process/risks  $\sigma_{c,t}^2$ 
  - i.e. education/year of birth/gender/age
- $e_{i,c,t}$ : to be specified later

# Perceived risks (PR)

• Income growth

$$\Delta y_{i,c,t+1} = \Delta z_{i,c,t+1} + \Delta e_{i,c,t+1}$$

• To the agent: **expected volatility** under FIRE

$$Var_{i,c,t}^*(\Delta y_{i,c,t+1}) = \sigma_{c,t+1|t}^2$$

• To econometricians: volatility

$$Var^{c}(\Delta \hat{e}_{i,c,t+1}) = \hat{\sigma}_{c,t}^{2} + \hat{\sigma}_{c,t+1}^{2} - 2Cov^{c}(\hat{e}_{i,c,t}, \hat{e}_{i,c,t+1})$$

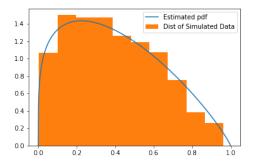

# Data and sample

- Density survey: SCE
  - 2013M6-2020M4 (monthly)
  - 1300 households
  - 12-month panel
- Income panel: PSID
  - 1970-1996 (annual), 1997-2017 (biennial)
  - approximately 5000 males/females
  - variable: wage/earning of household heads
  - stay in the sample for 11+ years
  - CPI adjusted
  - age 20-59
- Income Panel: SIPP
  - 2014M1-2019M12 (monthly)
  - earning from the primary job
  - 900-2700 respondents
  - CPI adjusted
  - age 20-59

# Survey question

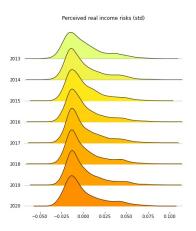

- Individual-specific bin-based forecast on  $\Delta y_{i,t+1}$ 
  - earning growth of the same job/position/hours
  - exl. endogenous labor supply changes/promotion/demotion/separation
- Measurement of PR:
  - variance:  $\overline{Var}_{i,t}(\Delta y_{i,t+1})$
- density estimation following Engelberg et al. (2009)
- restricted to attentive/high numeracy score sample
- adjusted into real terms using inflation uncertainty

#### An illustration of the density forecast estimation

- case 1. 3+ intervals with positive probs, to be fitted with a generalized beta distribution
- case 2. exactly 2 adjacent intervals with positive probs, to be fitted with a triangle distribution
- case 3. one interval only, to be fitted with a uniform distribution

#### Within-group dispersion in perceived income risks

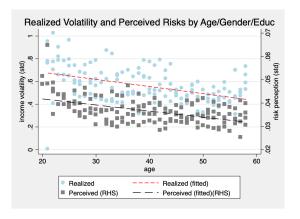

- residuals controlling for observables + time FE  $(R^2 = 0.07)$
- $\bullet$  average PR: 3.5% in std; 10/90 IQR: 5.2% in std

#### By age/gender/education

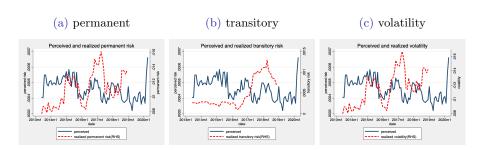

• e.g. a male high school graduate aged 30 growth by age/education by 5-yr of birth/education/gender

• consistent with Moffitt and Gottschalk (2002), Sabelhaus and Song (2010)

#### Time series structure of income shocks

$$e_{i,c,t} = \underbrace{log(p_{i,c,t})}_{\text{permanent}} + \underbrace{log(\theta_{i,c,t})}_{\text{transitory}}$$
$$log(p_{i,c,t+1}) = log(p_{i,c,t}) + log(\psi_{i,c,t+1})$$
$$log(\psi_{i,c,t}) \sim N(\frac{-\sigma_{c,t,\psi}^2}{2}, \sigma_{c,t,\psi}^2)$$
$$log(\theta_{i,c,t}) \sim N(\frac{-\sigma_{c,t,\psi}^2}{2}, \sigma_{c,t,\theta}^2)$$

# Permanent versus transitory risks (from monthly earning data)

- i.e. one-year-ahead perceived risk at 2014m1 v.s. realized risk over the same period
- monthly wage rate: earning per hour of work
- estimated monthly risks aggregated into annual frequency

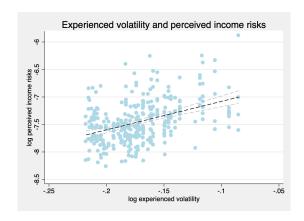

#### Perceptions versus economists' estimates

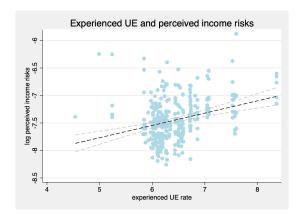

|                     | PerceivedRisk | PerceivedRisk(median) | RealizedGroupVolatility | RealizedPRisk | RealizedTRisk |
|---------------------|---------------|-----------------------|-------------------------|---------------|---------------|
| full sample (100%)  | 0.029         | 0.021                 | 0.090                   | 0.101         | 0.016         |
| gender              |               |                       |                         |               |               |
| 1 (50%)             | 0.030         | 0.022                 | 0.091                   | 0.102         | 0.016         |

| 30 (12%)            | 0.030         | 0.023                 | 0.091                   | 0.101         | 0.016         |
| 35 (13%)            | 0.029         | 0.021                 | 0.098                   | 0.101         | 0.016         |
| 40 (13%)            | 0.028         | 0.020                 | 0.084                   | 0.101         | 0.016         |
| 45 (14%)            | 0.028         | 0.020                 | 0.065                   | 0.101         | 0.016         |
| 50 (15%)            | 0.027         | 0.019                 | 0.078                   | 0.101         | 0.016         |
| 55 (15%)            | 0.027         | 0.018                 | 0.105                   | 0.100         | 0.016         |

#### Experienced income volatility and perceived risks

- income volatility conditional on macroeconomic history Storesletten et al. (2004)
- e.g. the experience by a 25-year old till 2015 is between 1990-2015

#### Experienced labor market and perceived risks

• e.g. experienced UE by a 25-year old in 2015 is between UE over 1990-2015

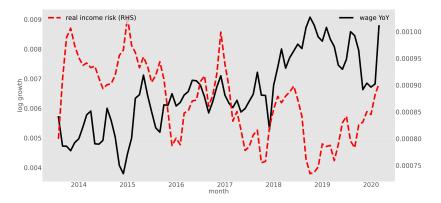

#### Extrapolation from individual experiences

- higher experienced volatility  $\rightarrow$  higher PR
- recent unemployment experience  $\rightarrow$  higher PR

|                      | (1)       | (2)       | (3)       | (4)       | (5)        | (6)        | (7)        | (8)        | (9)        | (10)       |

| Sample Size                      | 53178    | 53178    | 53178    | 53178    | 54584    | 6269     |
| Time FE                          | No       | Yes      | No       | Yes      | Yes      | No       |
| Individual FE                    | No       | No       | Yes      | Yes      | Yes      | Yes      |

• Higher perceived risks  $\rightarrow$  higher expected spending growth.

#### Taking stock

- People do have some clues
  - consistent with inter-group differences in income volatility
  - other covariates
    - \psi with education, household income, being a male
    - † with numeracy score, self-employed job, perceived individual UE risks, aggregate UE expectations, experienced volatility

#### Taking stock

- People do have some clues
  - consistent with inter-group differences in income volatility
  - other covariates
    - \( \psi \) with education, household income, being a male
    - † with numeracy score, self-employed job, perceived individual UE risks, aggregate UE expectations, experienced volatility
- But huge amount of heterogeneity remains
  - including all above:  $R^2 = 0.10$
  - individual fixed effects only:  $R^2 = 0.71$

#### Taking stock

- People do have some clues
  - consistent with inter-group differences in income volatility
  - other covariates
    - \( \psi \) with education, household income, being a male
    - † with numeracy score, self-employed job, perceived individual UE risks, aggregate UE expectations, experienced volatility
- But huge amount of heterogeneity remains
  - including all above:  $R^2 = 0.10$
  - individual fixed effects only:  $R^2 = 0.71$
- Possible explanations
  - "superior information" / unobserved heterogeneity
  - state dependence: aggregate economy conditions matter
  - past dependence: experiences matters Kuchler and Zafar (2019)
  - intrinsic heterogeneity: some are more uncertain than the other Ben-David et al. (2018)

- On level of aggregate savings

- On level of aggregate savings
  - $\bullet$  \ lower PR: lower precautionary saving motives  $\rightarrow$  less liquid holding  $\rightarrow$  higher MPC
  - ↑ state-dependence: a mean-preserving spread in risks → more precautionary savings Caballero (1990)

- On level of aggregate savings
  - $\bullet$  \ lower PR: lower precautionary saving motives  $\rightarrow$  less liquid holding  $\rightarrow$  higher MPC
  - ② ↑ state-dependence: a mean-preserving spread in risks → more
    precautionary savings Caballero (1990)
  - $\bullet$   $\uparrow$  extrapolation: lower income/unemployment  $\rightarrow$  higher PR  $\rightarrow$  intensified precautionary motive

- On level of aggregate savings

  - ↑ state-dependence: a mean-preserving spread in risks → more precautionary savings Caballero (1990)
  - る ↑ extrapolation: lower income/unemployment → higher PR → intensified precautionary motive
  - ◆ ↑ counter-cyclical risks: amplified business cycle fluctuations Bayer et al. (2019)

- On level of aggregate savings
  - $\bullet$  \ lower PR: lower precautionary saving motives  $\rightarrow$  less liquid  $holding \rightarrow higher MPC$
  - precautionary savings Caballero (1990)
  - $\bullet$  \( \text{\textrapolation: lower income/unemployment} \rightarrow \text{higher PR} \rightarrow \) intensified precautionary motive
  - ↑ counter-cyclical risks: amplified business cycle fluctuations Bayer et al. (2019)
- On wealth inequality
  - $\uparrow$  Direct effect: heterogeneous PR  $\rightarrow$  heterogeneity in saving/wealth
  - $\uparrow$  Indirect effect: lower PR  $\rightarrow$  lower self-insurance  $\rightarrow$  higher ex-post wealth inequality

#### Model overview

- Overlapping generation
- General equilibrium
- Uninsured idiosyncratic income risks
  - Permanent+ transitory productivity shock
  - Persistent unemployment spells
- No aggregate risk a la Krusell and Smith (1998)
- A blend of Huggett (1996) and Carroll (1997)
- Single one risk-free asset
- Allowing for subjective risk perceptions
  - Individuals swing between low/high risk perceptions

# Benchmark model (objective risk perceptions)

$$\max \quad \mathbb{E}\left[\sum_{\tau=0}^{\tau=L-1} (1-D)^{\tau} \beta^{\tau} u(c_{i,\tau})\right]$$

$$\underbrace{a_{i,\tau}}_{\text{Savings}} = \underbrace{m_{i,\tau}}_{\text{Cash in hand}} -c_{i,\tau}$$

$$b_{i,\tau+1} = a_{i,\tau} R$$

$$m_{i,\tau+1} = b_{i,\tau+1} + (1 - \underbrace{\lambda}_{\text{Income tax}}) y_{i,\tau+1}$$

$$a_{i,\tau} \ge 0$$

- CRRA:  $u(c) = \frac{c^{1-\rho}}{1-\rho}$
- Work age:  $\tau = 1, 2..., T$  (since entering job market)
- Life length:  $\tau = 1, 2..., L$  (since entering job market)
- Survival probability: 1-D

#### Income process

income

$$y_{i,\tau} = n_{i,\tau} W$$
$$n_{i,\tau} = p_{i,\tau} \xi_{i,\tau}$$

• permanent component

$$p_{i,\tau} = G_{\tau} p_{i,\tau-1} \psi_{i,\tau}, \quad log(\psi_{i,\tau}) \sim N(-\sigma_{\psi}^2/2, \sigma_{\psi}^2)$$

• persistent/transitory component

$$\xi_{i,\tau} = \begin{cases} \theta_{i,\tau} & \text{if} \quad \nu_{i,\tau} = e & \& \quad \tau \leq T, \quad log(\theta_{i,\tau}) \sim N(-\frac{\sigma_{\theta}^2}{2}, \sigma_{\theta}^2) \\ \zeta & \text{if} \quad \nu_{i,\tau} = u & \& \quad \tau \leq T \\ \mathbb{S} & \text{if} \quad \tau > T \end{cases}$$

• transition probability between  $\nu = u$  and  $\nu = e$ 

$$\pi(\nu_{\tau+1}|\nu_{\tau}) = \begin{bmatrix} \mathbf{0} & 1 - \mathbf{0} \\ 1 - E & \mathbf{E} \end{bmatrix}$$

# Objective versus subjective profile

- objective: agents perceive  $\Gamma = \{\sigma_{\psi}^2, \sigma_{\theta}^2, \mho, E\}$ income risk parameters
- subjective with state-dependence: each agent i swings between two subjective risk state  $\tilde{\Gamma}_{i,\tau} = \tilde{\Gamma}_l$  and  $\tilde{\Gamma}_{i,\tau} = \tilde{\Gamma}_h$ , with transition matrix  $\Omega$ .
  - heterogeneity in risk perceptions
- subjective model with extrapolation:  $\tilde{\Gamma}_{i,\tau}$  depends on employment status  $\nu_{i,\tau}$ , i.e.  $\tilde{\Gamma}_{i,\tau}(\nu_{i,\tau}=0)=\tilde{\Gamma}_l$  and  $\tilde{\Gamma}_{i,\tau}(\nu_{i,\tau}=1)=\tilde{\Gamma}_h$

#### Why subjective risk perceptions?

- I don't take a stance on if agents perceptions are correct or wrong
- It could be due to unobserved information to economists, or because of psychological reasons
- The subjective risk profile is disciplined by the survey data
- Risk parameters are exogenous to the model, therefore, does not contradict with rational expectation.

• Technology

$$Y = ZK^{\alpha}N^{1-\alpha}$$

Technology

$$Y = ZK^{\alpha}N^{1-\alpha}$$

• Government (balance budget)

$$\lambda \left[ 1 - \Pi^{\mho} + \zeta \Pi^{\mho} \right] = \zeta \Pi^{\mho} \tag{1}$$

Technology

$$Y = ZK^{\alpha}N^{1-\alpha}$$

• Government (balance budget)

$$\lambda \left[ 1 - \Pi^{\mho} + \zeta \Pi^{\mho} \right] = \zeta \Pi^{\mho} \tag{1}$$

- Demographics
  - Stable age distribution  $\{\mu_{\tau}\}_{\mu=1,2,..L}$

$$\mu_{\tau+1} = (1 - D)\mu_{\tau}$$

$$\sum_{\tau=1}^{L} \mu_{\tau} = 1$$

Technology

$$Y = ZK^{\alpha}N^{1-\alpha}$$

• Government (balance budget)

$$\lambda \left[ 1 - \Pi^{\mho} + \zeta \Pi^{\mho} \right] = \zeta \Pi^{\mho} \tag{1}$$

- Demographics
  - Stable age distribution  $\{\mu_{\tau}\}_{\mu=1,2,..L}$

$$\mu_{\tau+1} = (1 - D)\mu_{\tau}$$

$$\sum_{\tau=1}^{L} \mu_{\tau} = 1$$

- Accidental bequests
  - Newborn starts with a bank-balance equal to 0-1 fraction of the lump-sum of the accidental deceased's wealth

#### Value functions under different profiles

• objective:

$$\begin{split} V_{\tau}(\underbrace{\nu_{i,\tau}, m_{i,\tau}, p_{i,\tau}}) &= \max_{\{c_{i,\tau}, a_{i,\tau}\}} \ u(c_{i,\tau}) \\ &+ (1-D)\beta \mathbb{E}_{\tau} \left[ V_{\tau+1}((\nu_{i,\tau}, m_{i,\tau+1}, p_{i,\tau+1}) \right] \end{split}$$

• subjective:

$$\tilde{V}_{\tau}(\underbrace{\tilde{\Gamma}_{\tau}, \nu_{\tau}, m_{\tau}, p_{\tau}}_{\tilde{x}_{i,\tau}}) = \max_{\{c_{\tau}\}} u(c_{\tau}) + (1 - D)\beta \mathbb{E}_{\tau} \left[ \tilde{V}_{\tau+1}(\tilde{\Gamma}_{\tau+1}, \nu_{\tau}, m_{\tau+1}, p_{\tau+1}) \right]$$

#### Evolution of the distribution over state variables

• objective:

$$\psi_{\tau}(B) = \int_{x \in X} \underbrace{P(x, \tau - 1, B)}_{\text{transition funcs}} \psi_{\tau - 1} \quad \text{for all} \quad B \in B(X)$$

- B(X): distribution measure on state space X
- $\psi_{\tau}$ : distribution over state variables x for agents in age  $\tau$
- $\psi_1$  depends on initial draws of income shocks
- subjective:

$$\tilde{\psi}_{\tau}(\tilde{B}) = \int_{\tilde{\tau} \in \tilde{X}} \tilde{P}(\tilde{x}, \tau - 1, \tilde{B}) d\tilde{\psi}_{\tau - 1} \quad \text{for all} \quad \tilde{B} \in \tilde{B}(X)$$

#### Stationary equilibrium (StE)

- Optimal consumption and saving policies given  $W, R, \lambda$
- Distribution evolution consistent with optimal c and a policies and exogenous probabilities of income/beliefs
- The factor markets are clearing.

$$\sum_{\tau} \mu_{\tau} \int_{X} a(x, \tau) d\psi_{\tau} = K$$

$$\sum_{\tau=0}^{T-1} \mu_{\tau} \Pi_{\tau}^{E} = N$$

• Firm optimization under competitive factor markets.

$$W = Z(1 - \alpha)(K/N)^{\alpha}$$
  

$$R = 1 + Z\alpha(K/N)^{\alpha - 1} - \delta$$

- Newborn's bank balance equal to accidental bequests
- Balanced government budget

#### Estimation of subjective risk profile

$$\underbrace{\tilde{\Gamma}_{i,t}^{s}}_{\text{reported PR}} = \underbrace{\tilde{\Gamma}_{l} + \mathbb{1}(\underbrace{J_{i,t}}_{\tilde{\Gamma}_{i,t}} = 1)(\tilde{\Gamma}_{h} - \tilde{\Gamma}_{l})}_{\tilde{\Gamma}_{i,t}} + \xi_{t} + \eta_{i} + \epsilon_{i,t}$$

$$\underbrace{\tilde{\Gamma}_{i,t}^{s}}_{\tilde{\Gamma}_{i,t}} = 0$$

- $J_{i,t} = 0$  for low and = 1 for high PR state
- a short time series of  $\tilde{\Gamma}_{i,t}$  for many is observed in the survey
- $\{\tilde{\Gamma}_l \, \tilde{\Gamma}_h, \Omega\}$  can be estimated by MLE
- a modified Hamilton (1989) 2-regime-switching model
- $J_{i,t}$  can be also dependent upon business cycles

# Extensions: additional heterogeneity in MPC

- Heterogeneous time preferences
  - Ex-ante differences in  $\beta$ , a la Krusell and Smith (1998); Carroll et al. (2017); Krueger et al. (2016).
- Costly adjustments

$$\begin{aligned} V_{i,\tau}(c_{i,\tau-1}, x_{i,\tau}) &= \max \quad \{V_{\tau}^{A}(x_{i,\tau}) - \chi, V_{\tau}^{N}(c_{i,\tau-1}, x_{i,\tau})\} \\ V_{\tau}^{A}(x_{i,\tau}) &= \max_{\{c_{i,\tau}\}} \quad u(c_{i,\tau}) + (1-D)\beta \mathbb{E}_{\tau} \left[V_{\tau+1}(x_{i,\tau+1})\right] \\ V_{\tau}^{N}(c_{i,\tau-1}, x_{i,\tau}) &= u(c_{i,\tau-1}) + (1-D)\beta \mathbb{E}_{\tau} \left[V_{\tau+1}(c_{i,\tau}, x_{i,\tau+1})\right] \end{aligned}$$

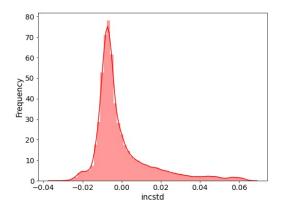

- Utility cost from adjusting consumption in each period
- $\bullet$  To introduce extensive margin of consumption change and match high MPC from data

#### Summary

- Survey data can inform incomplete-market macro models
  - Direct evidence for heterogeneity in perceptions that matter
  - Closer to agents' information set that truly affects their decisions
- No need to make stringent assumptions on expectation formation
- More work needed on understanding risk perception formation

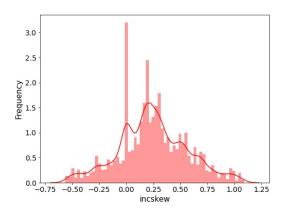

#### Within-group dispersion in nominal PR

- residuals controlling for observables /time fixed effects
- average PR: 2.1% in std; 10/90 IQR: 3.2% in std

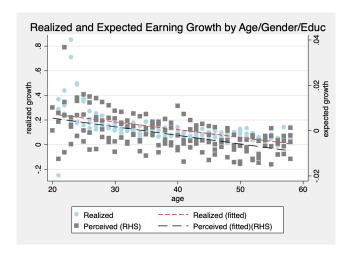

#### Within-group dispersion in PR skewness

• residuals controlling for observables / time fixed effects

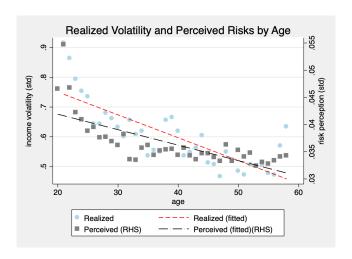

#### Appendix: expected growth by age

• e.g. a male high school graduate aged 30

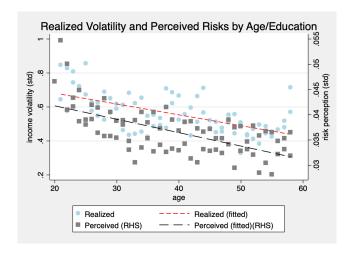

# Appendix: PR by age

• e.g. a 35-year old

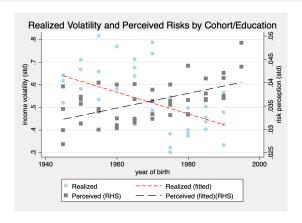

# Appendix: PR by age/education

• e.g. a 35-year old high school graduate

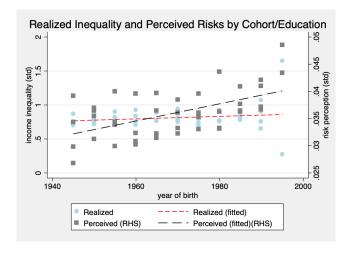

#### Appendix: PR by cohort/education/gender

- e.g. a male higher school graduate born between 1990-1995
- declining income volatlity between 1978-2013 Sabelhaus and Song (2010), Bloom et al. (2018)

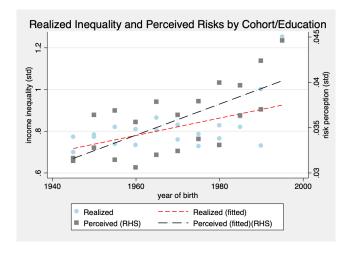

#### Appendix: PR by cohort

• e.g. a female college graduate born between 1970-1975

#### Appendix: PR by cohort/education

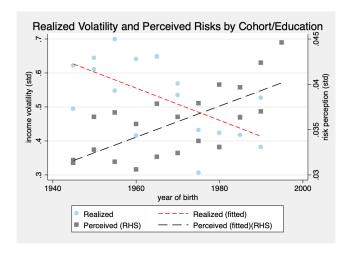

• e.g. a high school graduate born between 1985-1990

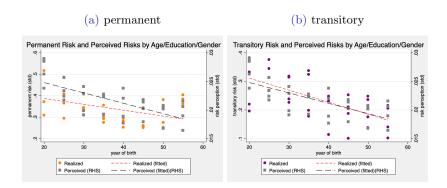

# Appendix: PR by cohort/education

• a college graduate born between 1985-1990

#### Permanent versus transitory risks

• e.g. a female high school graduate aged 30-35

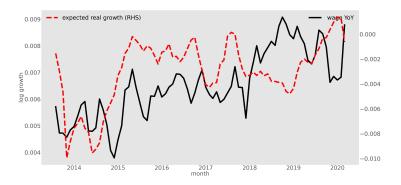

5-vr cohort/education/gender

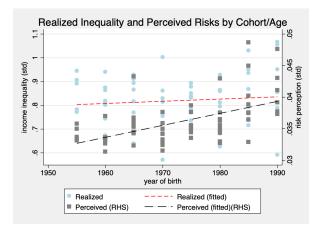

# Appendix: expected income growth and recent (past) wage growth

- $\bullet$   $\overline{\exp_t}$ : average expected growth across individuals
- quarterly growth in average hourly wage

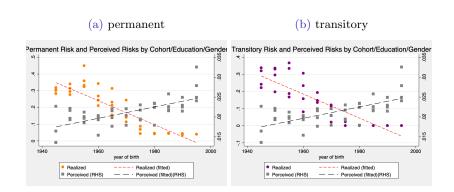

# Appendix: by 5-yr of birth/age

- e.g. a 25-year old born between 1985-1990
- only possible for post-2013 sample

#### Appendix: permanent versus transitory risks

• e.g. a female high school graduate born between 1985-1990

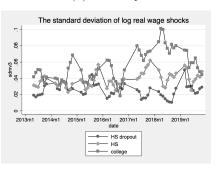

# Appendix: monthly earning inequality and volatility

# The standard deviation of log real wages The standard deviation of log real wages 2019m7 2019m1 2019m7 2019m1 2019m7 date HS dropout HS dropout HS college

#### (b) Volatility

#### Appendix: estimation of subjective risk profile

$$\log(\tilde{\text{var}}_{i,t}) = (12 + \frac{1}{12\kappa^2})\tilde{\sigma}_{i,t,\psi}^2 + \xi_t + \eta_i + \epsilon_{i,t}$$

•  $\kappa$ : externally assumed ratio of permanent and transitory risks  $\frac{\tilde{\sigma}_{i,t,\psi}}{\tilde{\sigma}_{i,t,\theta}}$
